

# Forces between magnets and multipole arrays of magnets: A Matlab implementation

Will Robertson

May 5, 2010

## Abstract

This is the user guide and documented implementation of a set of Matlab functions for calculating the forces (and stiffnesses) between cuboid permanent magnets and between multipole arrays of the same.

This document is still evolving. The documentation for the source code, especially, is rather unclear/non-existent at present. The user guide, however, should contain the bulk of the information needed to use this code.

(See Section 2 for installation instructions.)

## 1.1 Forces between magnets

The function `magnetforces` is used to calculate both forces and stiffnesses between magnets. The syntax is as follows:

```
forces = magnetforces(magnet_fixed, magnet_float, displ);
stiffnesses = magnetforces( ... , 'stiffness');
[f s] = magnetforces( ... , 'force', 'stiffness');
... = magnetforces( ... , 'x');
... = magnetforces( ... , 'y');
... = magnetforces( ... , 'z');
```

`magnetforces` takes three mandatory inputs to specify the position and magnetisation of the first and second magnets and the displacement between them. Optional arguments appended indicate whether to calculate force or stiffness or both and whether to calculate components in  $x$ - and/or  $y$ - and/or  $z$ - components respectively. The force<sup>1</sup> is calculated as that imposed on the second magnet; for this reason, I often call the first magnet the ‘fixed’ magnet and the second ‘floating’. If you wish to calculate the force on the first magnet instead, simply reverse the sign of the output.

**Inputs and outputs** The first two inputs are structures containing the following fields:

`magnet.dim` A  $(3 \times 1)$  vector of the side-lengths of the magnet.

`magnet.magn` The magnetisation magnitude of the magnet.

`magnet.magdir` A vector representing the direction of the magnetisation. This may be either a  $(3 \times 1)$  vector in cartesian coordinates or a  $(2 \times 1)$  vector in spherical coordinates.

In cartesian coordinates, the vector is interpreted as a unit vector; it is only used to calculate the direction of the magnetisation. In other words, writing  $[1;0;0]$  is the same as  $[2;0;0]$ , and so on. In spherical coordinates  $(\theta, \phi)$ ,  $\theta$  is the vertical projection of the angle around the  $x$ - $y$  plane ( $\theta = 0$  coincident with the  $x$ -axis), and  $\phi$  is the angle from the  $x$ - $y$  plane towards the  $z$ -axis. In other words, the following unit vectors are equivalent:

$$\begin{aligned}(1, 0, 0)_{\text{cartesian}} &\equiv (0, 0)_{\text{spherical}} \\ (0, 1, 0)_{\text{cartesian}} &\equiv (90, 0)_{\text{spherical}} \\ (0, 0, 1)_{\text{cartesian}} &\equiv (0, 90)_{\text{spherical}}\end{aligned}$$

---

<sup>1</sup>From now I will omit most mention of calculating stiffnesses; assume whenever I say ‘force’ I mean ‘force *and* stiffness’

N.B.  $\theta$  and  $\phi$  must be input in degrees, not radians. This seemingly odd decision was made in order to calculate quantities such as  $\cos(\pi/2) = 0$  exactly rather than to machine precision.

The third mandatory input is `displ`, which is a matrix of displacement vectors between the two magnets. `displ` should be a  $(3 \times D)$  matrix, where  $D$  is the number of displacements over which to calculate the forces. The size of `displ` dictates the size of the output force matrix; `forces` (etc.) will be also of size  $(3 \times D)$ .

**Example** Using `magnetforces` is rather simple. A magnet is set up as a simple structure like

```
magnet_fixed = struct(...
    'dim'      , [0.02 0.012 0.006], ...
    'magn'     , 0.38, ...
    'magdir'   , [0 0 1] ...
);
```

with something similar for `magnet_float`. The displacement matrix is then built up as a list of  $(3 \times 1)$  displacement vectors, such as

```
displ = [0; 0; 1]*linspace(0.01,0.03);
```

And that's about it. For a complete example, see `'examples/magnetforces_example.m'`.

## 1.2 Forces between multipole arrays of magnets

Because multipole arrays of magnets are more complex structures than single magnets, calculating the forces between them requires more setup as well. The syntax for calculating forces between multipole arrays follows the same style as for single magnets:

```
forces = multipoleforces(array_fixed, array_float, displ);
stiffnesses = multipoleforces( ... , 'stiffness');
[f s] = multipoleforces( ... , 'force', 'stiffness');
... = multipoleforces( ... , 'x');
... = multipoleforces( ... , 'y');
... = multipoleforces( ... , 'z');
```

Because multipole arrays can be defined in various ways, there are several overlapping methods for specifying the structures defining an array. Please excuse a certain amount of dryness in the information to follow; more inspiration for better documentation will come with feedback from those reading this document!

**Linear Halbach arrays** A minimal set of variables to define a linear multipole array are:

**array.type** Use ‘linear’ to specify an array of this type.  
**array.align** One of ‘x’, ‘y’, or ‘z’ to specify an alignment axis along which successive magnets are placed.  
**array.face** One of ‘+x’, ‘+y’, ‘+z’, ‘-x’, ‘-y’, or ‘-z’ to specify which direction the ‘strong’ side of the array faces.  
**array.msize** A  $(3 \times 1)$  vector defining the size of each magnet in the array.  
**array.Nmag** The number of magnets composing the array.  
**array.magn** The magnetisation magnitude of each magnet.  
**array.magdir\_rotate** The amount of rotation, in degrees, between successive magnets.

Notes:

- The array must **face** in a direction orthogonal to its alignment.
- ‘up’ and ‘down’ are defined as synonyms for facing ‘+z’ and ‘-z’, respectively, and ‘linear’ for array type ‘linear-x’.
- Singleton input to **msize** assumes a cube-shaped magnet.

The variables above are the minimum set required to specify a multipole array. In addition, the following array variables may be used instead of or as well as to specify the information in a different way:

**array.magdir\_first** This is the angle of magnetisation in degrees around the direction of magnetisation rotation for the first magnet. It defaults to  $\pm 90^\circ$  depending on the facing direction of the array.  
**array.length** The total length of the magnet array in the alignment direction of the array. If this variable is used then **width** and **height** (see below) must be as well.  
**array.width** The dimension of the array orthogonal to the alignment and facing directions.  
**array.height** The height of the array in the facing direction.  
**array.wavelength** The wavelength of magnetisation. Must be an integer number of magnet lengths.  
**array.Nwaves** The number of wavelengths of magnetisation in the array, which is probably always going to be an integer.  
**array.Nmag\_per\_wave** The number of magnets per wavelength of magnetisation (e.g., **Nmag\_per\_wave** of four is equivalent to **magdir\_rotate** of  $90^\circ$ ).  
**array.gap** Air-gap between successive magnet faces in the array. Defaults to zero.

Notes:

- **array.length+array.width+array.height** may be used as a synonymic replacement for **array.msize**.

- When using `Nwaves`, an additional magnet is placed on the end for symmetry.
- Setting `gap` does not affect `length` or `mlength`! That is, when `gap` is used, `length` refers to the total length of magnetic material placed end-to-end, not the total length of the array including the gaps.

**Planar Halbach arrays** Most of the information above follows for planar arrays, which can be thought of as a superposition of two orthogonal linear arrays.

`array.type` Use `'planar'` to specify an array of this type.

`array.align` One of `'xy'` (default), `'yz'`, or `'xz'` for a plane with which to align the array.

`array.width` This is now the `'length'` in the second spanning direction of the planar array. E.g., for the array `'planar-xy'`, `'length'` refers to the  $x$ -direction and `'width'` refers to the  $y$ -direction. (And `'height'` is  $z$ .)

`array.mwidth` Ditto for the width of each magnet in the array.

All other variables for linear Halbach arrays hold analogously for planar Halbach arrays; if desired, two-element input can be given to specify different properties in different directions.

**Planar quasi-Halbach arrays** This magnetisation pattern is simpler than the planar Halbach array described above.

`array.type` Use `'quasi-halbach'` to specify an array of this type.

`array.Nwaves` There are always four magnets per wavelength for the quasi-Halbach array. Two elements to specify the number of wavelengths in each direction, or just one if the same in both.

`array.Nmag` Instead of `Nwaves`, in case you want a non-integer number of wavelengths (but that would be weird).

### Patchwork planar array

`array.type` Use `'patchwork'` to specify an array of this type.

`array.Nmag` There isn't really a `'wavelength of magnetisation'` for this one; or rather, there is but it's trivial. So just define the number of magnets per side, instead. (Two-element for different sizes of one-element for an equal number of magnets in both directions.)

**Arbitrary arrays** Until now we have assumed that magnet arrays are composed of magnets with identical sizes and regularly-varying magnetisation directions. Some facilities are provided to generate more general/arbitrary-shaped arrays.

`array.type` Should be `'generic'` but may be omitted.

**array.mcount** The number of magnets in each direction, say  $(X, Y, Z)$ .  
**array.msize\_array** An  $(X, Y, Z, 3)$ -length matrix defining the magnet sizes for each magnet of the array.  
**array.magdir\_fn** An anonymous function that takes three input variables  $(i, j, k)$  to calculate the magnetisation for the  $(i, j, k)$ -th magnet in the  $(x, y, z)$ -directions respectively.  
**array.magn** At present this still must be singleton-valued. This will be amended at some stage to allow **magn\_array** input to be analogous with **msize** and **msize\_array**.

This approach for generating magnet arrays has been little-tested. Please inform me of associated problems if found.

## 2 Meta-information

**Obtaining** The latest version of this package may be obtained from the GitHub repository <http://github.com/wspr/magcode> with the following command:

```
git clone git://github.com/wspr/magcode.git
```

**Installing** It may be installed in Matlab simply by adding the ‘**matlab/**’ sub-directory to the Matlab path; e.g., adding the following to your **startup.m** file: (if that’s where you cloned the repository)

```
addpath ~/magcode/matlab
```

**Licensing** This work may be freely modified and distributed under the terms and conditions of the Apache License v2.0.<sup>2</sup> This work is Copyright 2009–2010 by Will Robertson.

**Contributing and feedback** Please report problems and suggestions at the GitHub issue tracker.<sup>3</sup>

The Matlab source code is written using Matlabweb.<sup>4</sup> After it is installed, use **mtangle magnetforces** to extract the Matlab files **magnetforces.m** and **multipoleforces.m**, as well as extracting the test suite (such as it is, for now). Running the Makefile with no targets (i.e., **make**) will perform this step as well as compiling the documentation you are currently reading.

About this file. This is a ‘literate programming’ approach to writing Matlab code using MATLABWEB<sup>5</sup>. To be honest I don’t know if it’s any better than simply using the Matlab programming language directly. The big advantage for me is that you have access to the entire L<sup>A</sup>T<sub>E</sub>X document environment, which

<sup>2</sup><http://www.apache.org/licenses/LICENSE-2.0>

<sup>3</sup><http://github.com/wspr/magnetocode/issues>

<sup>4</sup><http://www.ctan.org/tex-archive/web/matlabweb/>

<sup>5</sup><http://tug.ctan.org/pkg/matlabweb>

gives you access to vastly better tools for cross-referencing, maths typesetting, structured formatting, bibliography generation, and so on.

The downside is obviously that you miss out on Matlab's IDE with its integrated M-Lint program, debugger, profiler, and so on. Depending on one's work habits, this may be more or less of limiting factor to using literate programming in this way.

This work consists of the source file `magnetforces.web` and its associated derived files. It is released under the Apache License v2.0.<sup>6</sup>

This means, in essence, that you may freely modify and distribute this code provided that you acknowledge your changes to the work and retain my copyright. See the License text for the specific language governing permissions and limitations under the License.

Calculating forces between magnets. This is the source of some code to calculate the forces and/or stiffnesses between two cuboid-shaped magnets with arbitrary displacements and magnetisation direction. (A cuboid is like a three dimensional rectangle; its faces are all orthogonal but may have different side lengths.)

The main function is `magnetforces`, which takes three mandatory arguments: `magnet_fixed`, `magnet_float`, and `displ`. These will be described in more detail below.

Optional string arguments may be any combination of `'force'`, and/or `'stiffness'` to indicate which calculations should be output. If no calculation is specified, `'force'` is the default.

Inputs:	<code>magnet_fixed</code>	structure describing first magnet
	<code>magnet_float</code>	structure describing the second magnet
	<code>displ</code>	displacement between the magnets
	<code>[what to calculate]</code>	'force' and/or 'stiffness'
Outputs:	<code>forces</code>	forces on the second magnet
	<code>stiffnesses</code>	stiffnesses on the second magnet
Magnet properties:	<code>dim</code>	size of each magnet
	<code>magn</code>	magnetisation magnitude
	<code>magdir</code>	magnetisation direction

end

```

Variables and data structures. First of all, address the data structures required for the input and output. Because displacement of a single magnet has three components, plus sizes of the faces another three, plus magnetisation strength and direction (two) makes nine in total, we use one of Matlab's structures to pass the information into the function. Otherwise we'd have an overwhelming number of input arguments.

The input variables `magnet.dim` should be the entire side lengths of the magnets; these dimensions are halved when performing all of the calculations. (Because that's just how the maths is.)

We use spherical coordinates to represent magnetisation angle, where `phi` is the angle from the horizontal plane ( $-\pi/2 \leq \phi \leq \pi/2$ ) and `theta` is the angle around the horizontal plane ( $0 \leq \theta \leq 2\pi$ ). This follows Matlab's definition; other conventions are commonly used as well. Remember:

$$\begin{aligned}
 (1, 0, 0)_{\text{cartesian}} &\equiv (0, 0, 1)_{\text{spherical}} \\
 (0, 1, 0)_{\text{cartesian}} &\equiv (\pi/2, 0, 1)_{\text{spherical}} \\
 (0, 0, 1)_{\text{cartesian}} &\equiv (0, \pi/2, 1)_{\text{spherical}}
 \end{aligned}$$

Cartesian components can also be used as input as well, in which case they are made into a unit vector before multiplying it by the magnetisation magnitude. Either way (between spherical or cartesian input), J1 and J2 are made into the magnetisation vectors in cartesian coordinates.

```

8    < Initialise main variables 8>≡ (7) 22b>

    size1 = reshape(magnet_fixed.dim/2,[3 1]);
    size2 = reshape(magnet_float.dim/2,[3 1]);

    J1 = resolve_magnetisations(magnet_fixed.magn,magnet_fixed.magdir);
    J2 = resolve_magnetisations(magnet_float.magn,magnet_float.magdir);

```

Gotta check the displacement input for both functions. After sorting that out, we can initialise the output variables now we know how big they need to be.

9    *⟨ Organise input displacements 9 ⟩* ≡ (7 40a)

```
if size(displ,1) == 3
    % all good
elseif size(displ,2) == 3
    displ = transpose(displ);
else
    error(['Displacements matrix should be of size (3, D)',...
          'where D is the number of displacements.'])
end

Ndispl = size(displ,2);

if calc_force_bool
    forces_out = repmat(NaN,[3 Ndispl]);
end

if calc_stiffness_bool
    stiffnesses_out = repmat(NaN,[3 Ndispl]);
end
```

Wrangling user input and output. We now have a choice of calculations to take based on the user input. This chunk and the next are used in both `magnetforces.m` and `multipoleforces.m`.

```

10  < Parse calculation args 10>≡ (7 40a)

    debug_disp = @(str) disp([]);
    calc_force_bool = false;
    calc_stiffness_bool = false;

    % Undefined calculation flags for the three directions:
    calc_xyz = [-1 -1 -1];

    for ii = 1:length(varargin)
        switch varargin{ii}
            case 'debug',      debug_disp = @(str) disp(str);
            case 'force',      calc_force_bool      = true;
            case 'stiffness',  calc_stiffness_bool = true;
            case 'x',    calc_xyz(1) = 1;
            case 'y',    calc_xyz(2) = 1;
            case 'z',    calc_xyz(3) = 1;
            otherwise
                error(['Unknown calculation option ''',varargin{ii},'''])
            end
        end
    end

    % If none of 'x', 'y', 'z' are specified, calculate all.
    if all( calc_xyz == -1 )
        calc_xyz = [1 1 1];
    end

    calc_xyz( calc_xyz == -1 ) = 0;

    if ~calc_force_bool && ~calc_stiffness_bool
        calc_force_bool = true;
    end

```

After all of the calculations have occurred, they're placed back into `varargout`.  
(This happens at the very end, obviously.)

**11a**     $\langle$  *Return all results* **11a** $\rangle \equiv$  (7 40a)

```

ii = 0;
if calc_force_bool
    ii = ii + 1;
    varargout{ii} = forces_out;
end

if calc_stiffness_bool
    ii = ii + 1;
    varargout{ii} = stiffnesses_out;
end

```

The actual mechanics. The idea is that a multitude of displacements can be passed to the function and we iterate to generate a matrix of vector outputs.

**11b**     $\langle$  *Calculate for each displacement* **11b** $\rangle \equiv$  (7)

```

if calc_force_bool
    for ii = 1:Ndispl
        forces_out(:,ii) = single_magnet_force(displ(:,ii));
    end
end

if calc_stiffness_bool
    for ii = 1:Ndispl
        stiffnesses_out(:,ii) = single_magnet_stiffness(displ(:,ii));
    end
end

```

And this is what does the calculations.

12a  $\langle$  *Function for single force calculation* 12a $\rangle \equiv$  (7)

```

function force_out = single_magnet_force(displ)

force_components = repmat(NaN,[9 3]);

 $\langle$  Precompute displacement rotations 25b $\rangle$ 
 $\langle$  Print diagnostics 26c $\rangle$ 
 $\langle$  Calculate x force 13a $\rangle$ 
 $\langle$  Calculate y force 13b $\rangle$ 
 $\langle$  Calculate z force 12c $\rangle$ 

force_out = sum(force_components);
end

```

And this is what does the calculations for stiffness.

12b  $\langle$  *Function for single stiffness calculation* 12b $\rangle \equiv$  (7)

```

function stiffness_out = single_magnet_stiffness(displ)

stiffness_components = repmat(NaN,[9 3]);

 $\langle$  Precompute displacement rotations 25b $\rangle$ 
 $\langle$  Print diagnostics 26c $\rangle$ 
 $\langle$  Calculate stiffnesses 14 $\rangle$ 

stiffness_out = sum(stiffness_components);
end

```

The easy one first, where our magnetisation components align with the direction expected by the force functions.

12c  $\langle$  *Calculate z force* 12c $\rangle \equiv$  (12a)

```

debug_disp('z-z force:')
force_components(9,:) = forces_calc_z_z( size1,size2,displ,J1,J2 );

debug_disp('z-y force:')
force_components(8,:) = forces_calc_z_y( size1,size2,displ,J1,J2 );

debug_disp('z-x force:')
force_components(7,:) = forces_calc_z_x( size1,size2,displ,J1,J2 );

```

The other forces (i.e., x and y components) require a rotation to get the magnetisations correctly aligned. In the case of the magnet sizes, the lengths are just flipped rather than rotated (in rotation, sign is important). After the forces are calculated, rotate them back to the original coordinate system.

13a  $\langle$  Calculate x force 13a  $\rangle \equiv$  (12a)

```

calc_xyz = swap_x_z(calc_xyz);

debug_disp('Forces x-x:')
force_components(1,:) = ...
    rotate_z_to_x( forces_calc_z_z(size1_x,size2_x,d_x,J1_x,J2_x) );

debug_disp('Forces x-y:')
force_components(2,:) = ...
    rotate_z_to_x( forces_calc_z_y(size1_x,size2_x,d_x,J1_x,J2_x) );

debug_disp('Forces x-z:')
force_components(3,:) = ...
    rotate_z_to_x( forces_calc_z_x(size1_x,size2_x,d_x,J1_x,J2_x) );

calc_xyz = swap_x_z(calc_xyz);

```

Same again, this time making y the 'up' direction.

13b  $\langle$  Calculate y force 13b  $\rangle \equiv$  (12a)

```

calc_xyz = swap_y_z(calc_xyz);

debug_disp('Forces y-x:')
force_components(4,:) = ...
    rotate_z_to_y( forces_calc_z_x(size1_y,size2_y,d_y,J1_y,J2_y) );

debug_disp('Forces y-y:')
force_components(5,:) = ...
    rotate_z_to_y( forces_calc_z_z(size1_y,size2_y,d_y,J1_y,J2_y) );

debug_disp('Forces y-z:')
force_components(6,:) = ...
    rotate_z_to_y( forces_calc_z_y(size1_y,size2_y,d_y,J1_y,J2_y) );

calc_xyz = swap_y_z(calc_xyz);

```

Same as all the above. Except not really. Because stiffness isn't the same sort of vector quantity (if at all, really) as force, we simply 'flip' the directions around between different coordinate systems rather than rotate them.

```

14  < Calculate stiffnesses 14>≡ (12b)

debug_disp('z-x stiffness:')
stiffness_components(7,:) = ...
    stiffnesses_calc_z_x( size1,size2,displ,J1,J2 );

debug_disp('z-y stiffness:')
stiffness_components(8,:) = ...
    stiffnesses_calc_z_y( size1,size2,displ,J1,J2 );

debug_disp('z-z stiffness:')
stiffness_components(9,:) = ...
    stiffnesses_calc_z_z( size1,size2,displ,J1,J2 );

calc_xyz = swap_x_z(calc_xyz);

debug_disp('x-x stiffness:')
stiffness_components(1,:) = ...
    swap_x_z( stiffnesses_calc_z_z( size1_x,size2_x,d_x,J1_x,J2_x ) );

debug_disp('x-y stiffness:')
stiffness_components(2,:) = ...
    swap_x_z( stiffnesses_calc_z_y( size1_x,size2_x,d_x,J1_x,J2_x ) );

debug_disp('x-z stiffness:')
stiffness_components(3,:) = ...
    swap_x_z( stiffnesses_calc_z_x( size1_x,size2_x,d_x,J1_x,J2_x ) );

calc_xyz = swap_x_z(calc_xyz);

calc_xyz = swap_y_z(calc_xyz);

debug_disp('y-x stiffness:')
stiffness_components(4,:) = ...
    swap_y_z( stiffnesses_calc_z_x( size1_y,size2_y,d_y,J1_y,J2_y ) );

debug_disp('y-y stiffness:')
stiffness_components(5,:) = ...
    swap_y_z( stiffnesses_calc_z_z( size1_y,size2_y,d_y,J1_y,J2_y ) );

debug_disp('y-z stiffness:')
stiffness_components(6,:) = ...

```

```

swap_y_z( stiffnesses_calc_z_y( size1_y,size2_y,d_y,J1_y,J2_y ) );

calc_xyz = swap_y_z(calc_xyz);

```

Functions for calculating forces and stiffnesses. The calculations for forces between differently-oriented cuboid magnets are all directly from the literature. The stiffnesses have been derived by differentiating the force expressions, but that's the easy part.

$$\begin{aligned}
15 \quad \langle \textit{Functions for calculating forces and stiffnesses } 15 \rangle &\equiv (7) \\
&\langle \textit{Parallel magnets force calculation } 16 \rangle \\

*< Finish up 23>*

Orthogonal magnets forces given by Yonnet and Allag [2]. Note those equations seem to be written to calculate the force on the first magnet due to the second, so we negate all the values to get the force on the latter instead.

```

```
end
```

```
if calc_xyz(3)
```

```
    component_z = - component_x - component_y;
```

```
end
```

$\langle$  *Finish up* 23  $\rangle$

Orthogonal magnets stiffnesses derived from Yonnet and Allag [2]. First the  $z$ - $y$  magnetisation.

21a  $\langle$  Orthogonal magnets stiffness calculation 21a  $\rangle \equiv$  (15) 21b  $\triangleright$

```

function calc_out = stiffnesses_calc_z_y(size1,size2,offset,J1,J2)

J1 = J1(3);
J2 = J2(2);

 $\langle$  Initialise subfunction variables 22a  $\rangle$ 

if calc_xyz(1) calc_xyz(3)
    component_x = ((u.^2 .*v)./(u.^2 + v.^2)) + (u.^2 .*w)./(u.^2 + w.^2) ...
        - u.*atan1(v.*w,r.*u) + multiply_x_log_y( w , r + v ) + ...
        + multiply_x_log_y( v , r + w );
end

if calc_xyz(2) calc_xyz(3)
    component_y = - v/2 + (u.^2 .*v)./(u.^2 + v.^2) - (u.*v.*w)./(v.^2 + w.^2) ...
        - u.*atan1(u.*w,r.*v) - multiply_x_log_y( v , r + w );
end

if calc_xyz(3)
    component_z = - component_x - component_y;
end

 $\langle$  Finish up 23  $\rangle$ 

```

Now the  $z$ - $x$  magnetisation, which is  $z$ - $y$  rotated.

21b  $\langle$  Orthogonal magnets stiffness calculation 21a  $\rangle + \equiv$  (15) <21a

```

function calc_out = stiffnesses_calc_z_x(size1,size2,offset,J1,J2)

calc_xyz = swap_x_y(calc_xyz);

stiffnesses_xyz = stiffnesses_calc_z_y(...
    swap_x_y(size1), swap_x_y(size2), rotate_x_to_y(offset),...
    J1, rotate_x_to_y(J2) );

calc_xyz = swap_x_y(calc_xyz);
calc_out = swap_x_y(stiffnesses_xyz);

end

```

Some shared setup code. First `return` early if either of the magnetisations are zero — that’s the trivial solution. Assume that the magnetisation has already been rounded down to zero if necessary; i.e., that we don’t need to check for `J1` or `J2` are less than `1e-12` or whatever.

22a  $\langle$  *Initialise subfunction variables* 22a $\rangle \equiv$  (16 17 20 21a)

```
if (J1==0 J2==0)
    debug_disp('Zero magnetisation.')
    calc_out = [0; 0; 0];
    return;
end

u = offset(1) + size2(1)*(-1).^index_j - size1(1)*(-1).^index_i;
v = offset(2) + size2(2)*(-1).^index_l - size1(2)*(-1).^index_k;
w = offset(3) + size2(3)*(-1).^index_q - size1(3)*(-1).^index_p;
r = sqrt(u.^2+v.^2+w.^2);
```

Here are some variables used above that only need to be computed once. The idea here is to vectorise instead of using `for` loops because it allows more convenient manipulation of the data later on.

22b  $\langle$  *Initialise main variables* 8 $\rangle + \equiv$  (7) <8

```
magconst = 1/(4*pi*(4*pi*1e-7));

[index_i, index_j, index_k, index_l, index_p, index_q] = ndgrid([0 1]);

index_sum = (-1).^(index_i+index_j+index_k+index_l+index_p+index_q);
```

And some shared finishing code.

```
23  ⟨ Finish up 23⟩≡ (16 17 20 21a)

    if calc_xyz(1)
        component_x = index_sum.*component_x;
    else
        component_x = 0;
    end

    if calc_xyz(2)
        component_y = index_sum.*component_y;
    else
        component_y = 0;
    end

    if calc_xyz(3)
        component_z = index_sum.*component_z;
    else
        component_z = 0;
    end

    calc_out = J1*J2*magconst .* ...
        [ sum(component_x(:)) ;
          sum(component_y(:)) ;
          sum(component_z(:)) ] ;

    debug_disp(calc_out')

end
```

Setup code.

Magnetisation directions are specified in either cartesian or spherical coordinates. Since this is shared code, it's sent to the end to belong in a nested function.

We don't use Matlab's `sph2cart` here, because it doesn't calculate zero accurately (because it uses radians and `cos(pi/2)` can only be evaluated to machine precision of pi rather than symbolically).

24  $\langle$  *Function for resolving magnetisations* 24  $\rangle \equiv$  (7)

```
function J = resolve_magnetisations(magn,magdir)

if length(magdir)==2
    J_r = magn;
    J_t = magdir(1);
    J_p = magdir(2);
    J = [ J_r * cosd(J_p) * cosd(J_t) ; ...
          J_r * cosd(J_p) * sind(J_t) ; ...
          J_r * sind(J_p) ];
else
    if all(magdir == zeros(size(magdir)))
        J = [0; 0; 0];
    else
        J = magn*magdir/norm(magdir);
        J = reshape(J,[3 1]);
    end
end

end
```

Forces due to magnetisations in  $x$  and  $y$  are calculated by rotating the original expressions. The rotated magnet sizes and magnetisation vectors are calculated here once only.

The rotation matrices are precalculated to avoid performing the matrix multiplications each time.

25a  $\langle$  Precompute rotations 25a  $\rangle \equiv$  (7)

```

swap_x_y = @(vec) vec([2 1 3]);
swap_x_z = @(vec) vec([3 2 1]);
swap_y_z = @(vec) vec([1 3 2]);

rotate_z_to_x = @(vec) [ vec(3); vec(2); -vec(1) ] ; % Ry( 90)
rotate_x_to_z = @(vec) [ -vec(3); vec(2); vec(1) ] ; % Ry(-90)

rotate_y_to_z = @(vec) [ vec(1); -vec(3); vec(2) ] ; % Rx( 90)
rotate_z_to_y = @(vec) [ vec(1); vec(3); -vec(2) ] ; % Rx(-90)

rotate_x_to_y = @(vec) [ -vec(2); vec(1); vec(3) ] ; % Rz( 90)
rotate_y_to_x = @(vec) [ vec(2); -vec(1); vec(3) ] ; % Rz(-90)

size1_x = swap_x_z(size1);
size2_x = swap_x_z(size2);
J1_x    = rotate_x_to_z(J1);
J2_x    = rotate_x_to_z(J2);

size1_y = swap_y_z(size1);
size2_y = swap_y_z(size2);
J1_y    = rotate_y_to_z(J1);
J2_y    = rotate_y_to_z(J2);

```

And the rotated displacement vectors are calculated once per loop:

25b  $\langle$  Precompute displacement rotations 25b  $\rangle \equiv$  (12)

```

d_x = rotate_x_to_z(displ);
d_y = rotate_y_to_z(displ);

```

The equations contain two singularities. Specifically, the equations contain terms of the form  $x \log(y)$ , which becomes NaN when both  $x$  and  $y$  are zero since  $\log(0)$  is negative infinity.

This function computes  $x \log(y)$ , special-casing the singularity to output zero, instead. (This is indeed the value of the limit.)

26a  $\langle$  *Helper functions* 26a  $\rangle \equiv$  (15) 26b  $\triangleright$

```
function out = multiply_x_log_y(x,y)
    out = x.*log(y);
    out(~isfinite(out))=0;
end
```

Also, we're using `atan` instead of `atan2` (otherwise the wrong results are calculated — I guess I don't totally understand that), which becomes a problem when trying to compute `atan(0/0)` since `0/0` is NaN.

This function computes `atan` but takes two arguments.

26b  $\langle$  *Helper functions* 26a  $\rangle + \equiv$  (15)  $\triangleleft$  26a

```
function out = atan1(x,y)
    out = zeros(size(x));
    ind = x~=0 & y~=0;
    out(ind) = atan(x(ind)./y(ind));
end
```

Let's print some information to the terminal to aid debugging. This is especially important (for me) when looking at the rotated coordinate systems.

26c  $\langle$  *Print diagnostics* 26c  $\rangle \equiv$  (12)

```
debug_disp(' ')
debug_disp('CALCULATING THINGS')
debug_disp('=====')
debug_disp('Displacement:')
debug_disp(displ')
debug_disp('Magnetisations:')
debug_disp(J1')
debug_disp(J2')
```

When users type `help magnetforces` this is what they see.

```
27a < Matlab help text (forces) 27a>≡ (7)

%% MAGNETFORCES Calculate forces between two cuboid magnets
%
% Finish this off later. Please read the PDF documentation instead for now.
%
```

Test files. The chunks that follow are designed to be saved into individual files and executed automatically to check for (a) correctness and (b) regression problems as the code evolves.

How do I know if the code produces the correct forces? Well, for many cases I can compare with published values in the literature. Beyond that, I'll be setting up some tests that I can logically infer should produce the same results (such as mirror-image displacements) and test that.

There are many Matlab unit test frameworks but I'll be using a fairly low-tech method. In time this test suite should be (somehow) useable for all implementations of `magnetocode`, not just Matlab. But I haven't thought about doing anything like that, yet.

Because I'm lazy, just run the tests manually for now. This script must be run twice if it updates itself.

```
27b < testall.m 27b>≡ 61b>

clc;

test001a
test001b
test001c
test001d
```

Force testing. This test checks that square magnets produce the same forces in the each direction when displaced in positive and negative **x**, **y**, and **z** directions, respectively. In other words, this tests the function `forces_calc_z_y` directly. Both positive and negative magnetisations are used.

```

```

Forces between (multipole) magnet arrays. This function uses `magnetforces.m` to compute the forces between two multipole magnet arrays. As before, we can calculate either force and/or stiffness in all three directions.

The structure of the function itself should look fairly straightforward. Some of the code is repeated from `magnetforces` (an advantage of the literate programming approach) for parsing the inputs for which calculations to perform and return.

```

40a  < multipoleforces.m 40a>≡

      function [varargout] = multipoleforces(fixed_array, float_array, displ, varargin)

      < Matlab help text (multipole) 61a>

      < Parse calculation args 10>
      < Organise input displacements 9>
      < Initialise multipole variables 43>
      < Calculate array forces 42>
      < Return all results 11a>

      < Multipole sub-functions 40b>

      end

```

And nested sub-functions.

```

40b  < Multipole sub-functions 40b>≡                                     (40a)

      < Create arrays from input variables 45>
      < Extrapolate variables from input 60>

```

Table 1: Description of **multipoleforces** data structures.

Inputs:	<b>fixed_array</b>	structure describing first magnet array
	<b>float_array</b>	structure describing the second magnet array
	<b>displ</b>	displacement between first magnet of each array
	<i>[what to calculate]</i>	'force' and/or 'stiffness'
Outputs:	<b>forces</b>	forces on the second array
	<b>stiffnesses</b>	stiffnesses on the second array
Arrays:	<b>type</b>	See Table 2
	<b>align</b>	See Table 3
	<b>face</b>	See Table 4
	<b>mcount</b>	[i j k] magnets in each direction
	<b>msize</b>	size of each magnet
	<b>mgap</b>	gap between successive magnets
	<b>magn</b>	magnetisation magnitude
	<b>magdir_fn</b>	function to calculate the magnetisation direction

Table 2: Possibilities for the **type** of a multipole array.

<b>generic</b>	Magnetisation directions &c. are defined manually
<b>linear</b>	Linear Halbach array
<b>planar</b>	Planar Halbach array
<b>quasi-Halbach</b>	Quasi-Halbach planar array
<b>patchwork</b>	'Patchwork' planar array

Table 3: Axes or plane with which to align the array, set with **align**.

<b>x, y, z</b>	For linear arrays
<b>xy, yz, xz</b>	For planar arrays

Table 4: Facing direction for the strong side of the array, set with **face**.

<b>+x, -x</b>	Horizontal
<b>+y, -y</b>	Horizontal
<b>+z, -z, up, down</b>	Vertical

Although the input to these functions is described in the user guide, there's a quick summary in Tables 1 and 2.

Actual calculation of the forces. To calculate these forces, let's assume that we have two large arrays enumerating the positions and magnetisations of each individual magnet in each magnet array.

Required fields for each magnet array:

**total**  $M$  total number of magnets in the array  
**dim**  $(M \times 3)$  size of each magnet  
**magloc**  $(M \times 3)$  location of each magnet from the local coordinate system of the array  
**magn**  $(M \times 1)$  magnetisation magnitude of each magnet  
**magdir**  $(M \times 2)$  magnetisation direction of each magnet in spherical coordinates  
**size**  $(M \times 3)$  total actual dimensions of the array

Then it's just a matter of actually calculating each force and summing them together, as shown below. We'll discuss how to actually populate these data structures later.

```

42  < Calculate array forces 42>≡ (40a)

    for ii = 1:fixed_array.total

        fixed_magnet = struct(...
            'dim',    fixed_array.dim(ii,:), ...
            'magn',    fixed_array.magn(ii), ...
            'magdir', fixed_array.magdir(ii,:) ...
        );

        for jj = 1:float_array.total

            float_magnet = struct(...
                'dim',    float_array.dim(jj,:), ...
                'magn',    float_array.magn(jj), ...
                'magdir', float_array.magdir(jj,:) ...
            );

            mag_displ = displ_from_array_corners ...
                - repmat(fixed_array.magloc(ii,:),[1 Ndispl]) ...
                + repmat(float_array.magloc(jj,:),[1 Ndispl]) ;

            if calc_force_bool && ~calc_stiffness_bool
                array_forces(:, :, ii, jj) = ...
                    magnetforces(fixed_magnet, float_magnet, mag_displ, varargin{:});
            elseif calc_stiffness_bool && ~calc_force_bool
                array_stiffnesses(:, :, ii, jj) = ...
                    magnetforces(fixed_magnet, float_magnet, mag_displ, varargin{:});
            else

```

```

        [array_forces(:,:,ii,jj) array_stiffnesses(:,:,ii,jj)] = ...
            magnetforces(fixed_magnet, float_magnet, mag_displ,varargin{:});
    end

    end
end

if calc_force_bool
    forces_out = sum(sum(array_forces,4),3);
end

if calc_stiffness_bool
    stiffnesses_out = sum(sum(array_stiffnesses,4),3);
end

```

This is where it begins. This is basically just initialisation, but note the important `complete_array_from_input` function. This is what takes the high-level Halbach array (or whatever array) descriptions and translates them into a more direct (if tedious) form.

43    *⟨ Initialise multipole variables 43⟩* (40a)

```

    part = @(x,y) x(y);

    fixed_array = complete_array_from_input(fixed_array);
    float_array = complete_array_from_input(float_array);

    if calc_force_bool
        array_forces = repmat(NaN,[3 Ndispl fixed_array.total float_array.total]);
    end

    if calc_stiffness_bool
        array_stiffnesses = repmat(NaN,[3 Ndispl fixed_array.total float_array.total]);
    end

    displ_from_array_corners = displ ...
        + repmat(fixed_array.size/2,[1 Ndispl]) ...
        - repmat(float_array.size/2,[1 Ndispl]);

```

From user input to array generation. We separate the force calculation from transforming the inputs into an intermediate form used for that purpose. This will hopefully allow us a little more flexibility.

This is the magic abstraction behind `complete_array_from_input` that allows us to write readable input code describing multipole arrays in as little detail as possible.

As input variables for a linear multipole array, we want to use some combination of the following:

- $w$  wavelength of magnetisation
- $l$  length of the array without magnet gaps
- $N$  number of wavelengths
- $d$  magnet length
- $T$  total number of magnets
- $M$  number of magnets per wavelength
- $\phi$  rotation between successive magnets

These are related via the following equations of constraint:

$$w = Md \quad l = Td \quad N = T/M \quad M = 360^\circ/\phi \quad (1)$$

Taking logarithms and writing in matrix form yields

$$\begin{bmatrix} 1 & 0 & 0 & -1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 \end{bmatrix} \log \begin{bmatrix} w \\ l \\ N \\ d \\ T \\ M \\ \phi \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \log(360^\circ) \end{bmatrix} \quad (2)$$

We can use this matrix to compute whichever variables we need given enough inputs.

However, we generally do not want an integer number of wavelengths of magnetisation in the magnet arrays; if  $T = MN$  then we get small lateral forces that are undesirable for stability. We prefer instead to have  $T = MN + 1$ , but this cannot be represented by our linear (after taking logarithms) algebra above. Therefore, if the user requests a total number of wavelengths of magnetisation, we automatically add one end magnet to restore the symmetry of the forces.

More variables that can be set are:

- $\phi_0$  magnetisation direction of the first magnet
- $g$  additional gap between adjacent magnet faces (optional)
- $e$  array height (or magnet height)
- $f$  array width (or magnet width)

For both technical reasons and reasons of convenience, the length of the array  $l$  does not take into account any specified magnet gap  $g$ . In other words,  $l$  is

actually the length of the possibly discontinuous magnetic material; the length of the array will be  $l + (N - 1)g$ .

45     $\langle$  Create arrays from input variables 45  $\rangle \equiv$  (40b)

```

```
 $\langle$  Fill in array structures 46  $\rangle$ 
```

```
end
```

This is the part where those big data structures are filled up based on the user input data. I guess you could consider the process to consist of three stages. User input is the most abstract, from which the code above infers the other variables that have only been implied. Then the following code uses all that to construct a most basic description of the arrays, literally a listing of each magnet, its dimensions and position, and its magnetisation vector.

```

46  < Fill in array structures 46>≡ (45)

array.magloc = repmat(NaN,[array.total 3]);
array.magdir = array.magloc;
arrat.magloc_array = repmat(NaN,[array.mcount(1) array.mcount(2) array.mcount(3) 3]);

nn = 0;
for iii = 1:array.mcount(1)
    for jjj = 1:array.mcount(2)
        for kkk = 1:array.mcount(3)
            nn = nn + 1;
            array.magdir(nn,:) = array.magdir_fn(iii,jjj,kkk);
        end
    end
end

magsep_x = zeros(size(array.mcount(1)));
magsep_y = zeros(size(array.mcount(2)));
magsep_z = zeros(size(array.mcount(3)));

magsep_x(1) = array.msize_array(1,1,1,1)/2;
magsep_y(1) = array.msize_array(1,1,1,2)/2;
magsep_z(1) = array.msize_array(1,1,1,3)/2;

for iii = 2:array.mcount(1)
    magsep_x(iii) = array.msize_array(iii-1,1,1,1)/2 ...
        + array.msize_array(iii ,1,1,1)/2 ;
end
