Forces between magnets and multipole arrays of magnets: A Matlab implementation

Will Robertson

May 5, 2010

Abstract

This is the user guide and documented implementation of a set of Matlab functions for calculating the forces (and stiffnesses) between cuboid permanent magnets and between multipole arrays of the same.

This document is still evolving. The documentation for the source code, especially, is rather unclear/non-existent at present. The user guide, however, should contain the bulk of the information needed to use this code.

(See Section 2 for installation instructions.)

1.1 Forces between magnets

The function magnetforces is used to calculate both forces and stiffnesses between magnets. The syntax is as follows:

```
forces = magnetforces(magnet_fixed, magnet_float, displ);
stiffnesses = magnetforces( ... , 'stiffness');
    [f s] = magnetforces( ... , 'force', 'stiffness');
    ... = magnetforces( ... , 'x');
    ... = magnetforces( ... , 'y');
    ... = magnetforces( ... , 'z');
```

magnetforces takes three mandatory inputs to specify the position and magnetisation of the first and second magnets and the displacement between them. Optional arguments appended indicate whether to calculate force or stiffness or both and whether to calculate components in x- and/or y- and/or z- components respectively. The force is calculated as that imposed on the second magnet; for this reason, I often call the first magnet the 'fixed' magnet and the second 'floating'. If you wish to calculate the force on the first magnet instead, simply reverse the sign of the output.

Inputs and outputs The first two inputs are structures containing the following fields:

```
{\tt magnet.dim}\ A\ (3\times 1) vector of the side-lengths of the magnet.
```

magnet.magn The magnetisation magnitude of the magnet.

magnet.magdir A vector representing the direction of the magnetisation. This may be either a (3×1) vector in cartesian coordinates or a (2×1) vector in spherical coordinates.

In cartesian coordinates, the vector is interpreted as a unit vector; it is only used to calculate the direction of the magnetisation. In other words, writing [1;0;0] is the same as [2;0;0], and so on. In spherical coordinates (θ, ϕ) , θ is the vertical projection of the angle around the x-y plane $(\theta = 0$ coincident with the x-axis), and ϕ is the angle from the x-y plane towards the z-axis. In other words, the following unit vectors are equivalent:

```
(1,0,0)_{\text{cartesian}} \equiv (0,0)_{\text{spherical}}

(0,1,0)_{\text{cartesian}} \equiv (90,0)_{\text{spherical}}

(0,0,1)_{\text{cartesian}} \equiv (0,90)_{\text{spherical}}
```

 $^{^1{\}rm From}$ now I will omit most mention of calculating stiffnesses; assume whenever I say 'force' I mean 'force and stiffness'

N.B. θ and ϕ must be input in degrees, not radians. This seemingly odd decision was made in order to calculate quantities such as $\cos(\pi/2) = 0$ exactly rather than to machine precision.

The third mandatory input is displ, which is a matrix of displacement vectors between the two magnets. displ should be a $(3 \times D)$ matrix, where D is the number of displacements over which to calculate the forces. The size of displ dictates the size of the output force matrix; forces (etc.) will be also of size $(3 \times D)$.

Example Using magnetforces is rather simple. A magnet is set up as a simple structure like

```
magnet_fixed = struct(...
  'dim' , [0.02 0.012 0.006], ...
  'magn' , 0.38, ...
  'magdir', [0 0 1] ...
);
```

with something similar for magnet_float. The displacement matrix is then built up as a list of (3×1) displacement vectors, such as

```
displ = [0; 0; 1]*linspace(0.01,0.03);
```

And that's about it. For a complete example, see 'examples/magnetforces_example.m'.

1.2 Forces between multipole arrays of magnets

Because multipole arrays of magnets are more complex structures than single magnets, calculating the forces between them requires more setup as well. The syntax for calculating forces between multipole arrays follows the same style as for single magnets:

```
forces = multipoleforces(array_fixed, array_float, displ);
stiffnesses = multipoleforces( ... , 'stiffness');
    [f s] = multipoleforces( ... , 'force', 'stiffness');
    ... = multipoleforces( ... , 'x');
    ... = multipoleforces( ... , 'y');
    ... = multipoleforces( ... , 'z');
```

Because multipole arrays can be defined in various ways, there are several overlapping methods for specifying the structures defining an array. Please escuse a certain amount of dryness in the information to follow; more inspiration for better documentation will come with feedback from those reading this document!

Linear Halbach arrays A minimal set of variables to define a linear multipole array are:

array.type Use 'linear' to specify an array of this type.

array.align One of 'x', 'y', or 'z' to specify an alignment axis along which successive magnets are placed.

array.face One of '+x', '+y', '+z', '-x', '-y', or '-z' to specify which direction the 'strong' side of the array faces.

array.msize A (3×1) vector defining the size of each magnet in the array.

array. Nmag The number of magnets composing the array.

array.magn The magnetisation magnitude of each magnet.

array.magdir_rotate The amount of rotation, in degrees, between successive magnets.

Notes:

- The array must face in a direction orthogonal to its alignment.
- 'up' and 'down' are defined as synonyms for facing '+z' and '-z', respectively, and 'linear' for array type 'linear-x'.
- Singleton input to msize assumes a cube-shaped magnet.

The variables above are the minimum set required to specify a multipole array. In addition, the following array variables may be used instead of or as well as to specify the information in a different way:

array.magdir_first This is the angle of magnetisation in degrees around the direction of magnetisation rotation for the first magnet. It defaults to ±90° depending on the facing direction of the array.

array.length The total length of the magnet array in the alignment direction of the array. If this variable is used then width and height (see below) must be as well.

array.width The dimension of the array orthogonal to the alignment and facing directions.

array.height The height of the array in the facing direction.

array.wavelength The wavelength of magnetisation. Must be an integer number of magnet lengths.

array. Nwaves The number of wavelengths of magnetisation in the array, which is probably always going to be an integer.

array.Nmag_per_wave The number of magnets per wavelength of magnetisation (e.g., Nmag_per_wave of four is equivalent to magdir_rotate of 90°).

array.gap Air-gap between successive magnet faces in the array. Defaults to zero.

Notes:

• array.mlength+array.width+array.height may be used as a synonymic replacement for array.msize.

- When using Nwaves, an additional magnet is placed on the end for symmetry.
- Setting gap does not affect length or mlength! That is, when gap is used, length refers to the total length of magnetic material placed end-to-end, not the total length of the array including the gaps.

Planar Halbach arrays Most of the information above follows for planar arrays, which can be thought of as a superposition of two orthogonal linear arrays.

array.type Use 'planar' to specify an array of this type.

array.align One of 'xy' (default), 'yz', or 'xz' for a plane with which to align the array.

array.width This is now the 'length' in the second spanning direction of the planar array. E.g., for the array 'planar-xy', 'length' refers to the x-direction and 'width' refers to the y-direction. (And 'height' is z.)

array.mwidth Ditto for the width of each magnet in the array.

All other variables for linear Halbach arrays hold analogously for planar Halbach arrays; if desired, two-element input can be given to specify different properties in different directions.

Planar quasi-Halbach arrays This magnetisation pattern is simpler than the planar Halbach array described above.

array.type Use 'quasi-halbach' to specify an array of this type.

array. Nwaves There are always four magnets per wavelength for the quasi-Halbach array. Two elements to specify the number of wavelengths in each direction, or just one if the same in both.

array.Nmag Instead of Nwaves, in case you want a non-integer number of wavelengths (but that would be weird).

Patchwork planar array

array.type Use 'patchwork' to specify an array of this type.

array. Nmag There isn't really a 'wavelength of magnetisation' for this one; or rather, there is but it's trivial. So just define the number of magnets per side, instead. (Two-element for different sizes of one-element for an equal number of magnets in both directions.)

Arbitrary arrays Until now we have assumed that magnet arrays are composed of magnets with identical sizes and regularly-varying magnetisation directions. Some facilities are provided to generate more general/arbitrary—shaped arrays.

array.type Should be 'generic' but may be omitted.

array.mcount The number of magnets in each direction, say (X, Y, Z).

array.msize_array An (X, Y, Z, 3)-length matrix defining the magnet sizes for each magnet of the array.

- array.magdir_fn An anonymous function that takes three input variables (i, j, k) to calculate the magnetisation for the (i, j, k)-th magnet in the (x, y, z)-directions respectively.
- array.magn At present this still must be singleton-valued. This will be amended at some stage to allow magn_array input to be analogous with msize and msize_array.

This approach for generating magnet arrays has been little-tested. Please inform me of associated problems if found.

2 Meta-information

Obtaining The latest version of this package may be obtained from the GitHub repository http://github.com/wspr/magcode with the following command:

```
git clone git://github.com/wspr/magcode.git
```

Installing It may be installed in Matlab simply by adding the 'matlab/' sub-directory to the Matlab path; e.g., adding the following to your startup.m file: (if that's where you cloned the repository)

```
addpath ~/magcode/matlab
```

Licensing This work may be freely modified and distributed under the terms and conditions of the Apache License v2.0.² This work is Copyright 2009–2010 by Will Robertson.

Contributing and feedback Please report problems and suggestions at the GitHub issue tracker.³

The Matlab source code is written using Matlabweb.⁴ After it is installed, use mtangle magnetforces to extract the Matlab files magnetforces.m and multipoleforces.m, as well as extracting the test suite (such as it is, for now). Running the Makefile with no targets (i.e., make) will perform this step as well as compiling the documentation you are currently reading.

About this file. This is a 'literate programming' approach to writing Matlab code using MATLABWEB⁵. To be honest I don't know if it's any better than simply using the Matlab programming language directly. The big advantage for me is that you have access to the entire I^ATEX document environment, which

²http://www.apache.org/licenses/LICENSE-2.0

³http://github.com/wspr/magnetocode/issues

⁴http://www.ctan.org/tex-archive/web/matlabweb/

⁵http://tug.ctan.org/pkg/matlabweb

gives you access to vastly better tools for cross-referencing, maths typesetting, structured formatting, bibliography generation, and so on.

The downside is obviously that you miss out on Matlab's IDE with its integrated M-Lint program, debugger, profiler, and so on. Depending on one's work habits, this may be more or less of limiting factor to using literate programming in this way.

This work consists of the source file magnetforces.web and its associated derived files. It is released under the Apache License v2.0.6

This means, in essense, that you may freely modify and distribute this code provided that you acknowledge your changes to the work and retain my copyright. See the License text for the specific language governing permissions and limitations under the License.

Calculating forces between magnets. This is the source of some code to calculate the forces and/or stiffnesses between two cuboid-shaped magnets with arbitary displacements and magnetisation direction. (A cuboid is like a three dimensional rectangle; its faces are all orthogonal but may have different side lengths.)

The main function is magnetforces, which takes three mandatory arguments: magnet_fixed, magnet_float, and displ. These will be described in more detail below.

Optional string arguments may be any combination of 'force', and/or 'stiffness' to indicate which calculations should be output. If no calculation is specified, 'force' is the default.

Inputs:	magnet_fixed	structure describing first magnet
	magnet_float	structure describing the second magnet
	displ	displacement between the magnets
	[what to calculate]	'force' and/or 'stiffness'
Outputs:	forces	forces on the second magnet
	stiffnesses	stiffnesses on the second magnet
Magnet properties:	dim	size of each magnet
	magn	magnetisation magnitude
	magdir	magnetisation direction

 $\langle magnet forces.m \rangle \equiv$

function [varargout] = magnetforces(magnet_fixed, magnet_float, displ, varargin)

```
⟨ Matlab help text (forces) 27a⟩

⟨ Parse calculation args 10⟩
⟨ Organise input displacements 9⟩
⟨ Initialise main variables 8⟩
⟨ Precompute rotations 25a⟩
```

 $^{^{6} \}verb|http://www.apache.org/licenses/LICENSE-2.0|$

```
⟨ Calculate for each displacement 11b⟩
⟨ Return all results 11a⟩
⟨ Function for resolving magnetisations 24⟩
⟨ Function for single force calculation 12a⟩
⟨ Function for single stiffness calculation 12b⟩
⟨ Functions for calculating forces and stiffnesses 15⟩
end
```

Variables and data structures. First of all, address the data structures required for the input and output. Because displacement of a single magnet has three components, plus sizes of the faces another three, plus magnetisation strength and direction (two) makes nine in total, we use one of Matlab's structures to pass the information into the function. Otherwise we'd have an overwhelming number of input arguments.

The input variables magnet.dim should be the entire side lengths of the magnets; these dimensions are halved when performing all of the calculations. (Because that's just how the maths is.)

We use spherical coordinates to represent magnetisation angle, where **phi** is the angle from the horizontal plane $(-\pi/2 \le \phi \le \pi/2)$ and **theta** is the angle around the horizontal plane $(0 \le \theta \le 2\pi)$. This follows Matlab's definition; other conventions are commonly used as well. Remember:

```
(1,0,0)_{\text{cartesian}} \equiv (0,0,1)_{\text{spherical}}

(0,1,0)_{\text{cartesian}} \equiv (\pi/2,0,1)_{\text{spherical}}

(0,0,1)_{\text{cartesian}} \equiv (0,\pi/2,1)_{\text{spherical}}
```

Cartesian components can also be used as input as well, in which case they are made into a unit vector before multiplying it by the magnetisation magnitude. Either way (between spherical or cartesian input), J1 and J2 are made into the magnetisation vectors in cartesian coordinates.

```
8  \langle Initialise main variables 8 \rangle = (7) 22b \rangle
    size1 = reshape(magnet_fixed.dim/2,[3 1]);
    size2 = reshape(magnet_float.dim/2,[3 1]);

J1 = resolve_magnetisations(magnet_fixed.magn,magnet_fixed.magdir);
    J2 = resolve_magnetisations(magnet_float.magn,magnet_float.magdir);
```

Gotta check the displacement input for both functions. After sorting that out, we can initialise the output variables now we know how big they need to me.

Wrangling user input and output. We now have a choice of calculations to take based on the user input. This chunk and the next are used in both magnetforces.m and multipoleforces.m.

```
10
     \langle Parse\ calculation\ args\ 10 \rangle \equiv
                                                                     (7 40a)
       debug_disp = @(str) disp([]);
       calc_force_bool = false;
       calc_stiffness_bool = false;
       % Undefined calculation flags for the three directions:
       calc_xyz = [-1 -1 -1];
       for ii = 1:length(varargin)
         switch varargin{ii}
                               debug_disp = @(str) disp(str);
           case 'debug',
                               calc_force_bool
                                                   = true;
            case 'force',
            case 'stiffness', calc_stiffness_bool = true;
            case 'x', calc_xyz(1) = 1;
           case 'y', calc_xyz(2) = 1;
            case 'z', calc_xyz(3) = 1;
           otherwise
              error(['Unknown calculation option ''', varargin{ii},'"'])
         end
       end
       \% If none of 'x', 'y', 'z' are specified, calculate all.
       if all( calc_xyz == -1 )
         calc_xyz = [1 1 1];
       end
       calc_xyz(calc_xyz == -1) = 0;
       if ~calc_force_bool && ~calc_stiffness_bool
         calc_force_bool = true;
       end
```

After all of the calculations have occured, they're placed back into varargout. (This happens at the very end, obviously.)

The actual mechanics. The idea is that a multitude of displacements can be passed to the function and we iterate to generate a matrix of vector outputs.

```
if calc_force_bool
    for ii = 1:Ndispl
        forces_out(:,ii) = single_magnet_force(displ(:,ii));
    end
end

if calc_stiffness_bool
    for ii = 1:Ndispl
        stiffnesses_out(:,ii) = single_magnet_stiffness(displ(:,ii));
    end
end
```

```
And this is what does the calculations.
        \langle Function for single force calculation 12a \rangle \equiv
12a
                                                                                     (7)
          function force_out = single_magnet_force(displ)
          force_components = repmat(NaN,[9 3]);
          ⟨ Precompute displacement rotations 25b⟩
           ⟨ Print diagnostics 26c⟩
          ⟨ Calculate x force 13a⟩
          ⟨ Calculate y force 13b⟩
          ⟨ Calculate z force 12c⟩
          force_out = sum(force_components);
          end
        And this is what does the calculations for stiffness.
        \langle Function for single stiffness calculation 12b \rangle \equiv
12b
                                                                                     (7)
          function stiffness_out = single_magnet_stiffness(displ)
          stiffness_components = repmat(NaN,[9 3]);
          ⟨ Precompute displacement rotations 25b⟩
          \langle Print \ diagnostics \ 26c \rangle
          ⟨ Calculate stiffnesses 14⟩
          stiffness_out = sum(stiffness_components);
          end
        The easy one first, where our magnetisation components align with the direction
        expected by the force functions.
        \langle Calculate z force 12c \rangle \equiv
12c
                                                                                   (12a)
          debug_disp('z-z force:')
          force_components(9,:) = forces_calc_z_z( size1,size2,disp1,J1,J2 );
          debug_disp('z-y force:')
          force_components(8,:) = forces_calc_z_y( size1,size2,displ,J1,J2 );
```

force_components(7,:) = forces_calc_z_x(size1,size2,displ,J1,J2);

debug_disp('z-x force:')

The other forces (i.e., x and y components) require a rotation to get the magnetisations correctly aligned. In the case of the magnet sizes, the lengths are just flipped rather than rotated (in rotation, sign is important). After the forces are calculated, rotate them back to the original coordinate system.

```
\langle Calculate \times force \ 13a \rangle \equiv
13a
                                                                           (12a)
         calc_xyz = swap_x_z(calc_xyz);
         debug_disp('Forces x-x:')
         force_components(1,:) = ...
           rotate_z_to_x( forces_calc_z_z(size1_x,size2_x,d_x,J1_x,J2_x) );
         debug_disp('Forces x-y:')
         force_components(2,:) = ...
           rotate_z_to_x( forces_calc_z_y(size1_x,size2_x,d_x,J1_x,J2_x) );
         debug_disp('Forces x-z:')
         force_components(3,:) = ...
           rotate_z_to_x( forces_calc_z_x(size1_x,size2_x,d_x,J1_x,J2_x) );
         calc_xyz = swap_x_z(calc_xyz);
       Same again, this time making y the 'up' direction.
       \langle Calculate y force 13b \rangle \equiv
13b
                                                                           (12a)
         calc_xyz = swap_y_z(calc_xyz);
         debug_disp('Forces y-x:')
         force_components(4,:) = ...
           rotate_z_to_y( forces_calc_z_x(size1_y,size2_y,d_y,J1_y,J2_y) );
         debug_disp('Forces y-y:')
         force_components(5,:) = ...
           rotate_z_to_y( forces_calc_z_z(size1_y,size2_y,d_y,J1_y,J2_y) );
         debug_disp('Forces y-z:')
         force_components(6,:) = ...
           rotate_z_to_y( forces_calc_z_y(size1_y,size2_y,d_y,J1_y,J2_y) );
         calc_xyz = swap_y_z(calc_xyz);
```

Same as all the above. Except not really. Because stiffness isn't the same sort of vector quantity (if at all, really) as force, we simply 'flip' the directions around between different coordinate systems rather than rotate them.

```
14
     \langle Calculate stiffnesses 14 \rangle \equiv
                                                                      (12b)
       debug_disp('z-x stiffness:')
       stiffness_components(7,:) = ...
          stiffnesses_calc_z_x( size1,size2,displ,J1,J2 );
       debug_disp('z-y stiffness:')
       stiffness_components(8,:) = ...
          stiffnesses_calc_z_y( size1,size2,displ,J1,J2 );
       debug_disp('z-z stiffness:')
       stiffness_components(9,:) = ...
          stiffnesses_calc_z_z( size1,size2,displ,J1,J2 );
       calc_xyz = swap_x_z(calc_xyz);
       debug_disp('x-x stiffness:')
       stiffness_components(1,:) = ...
         swap_x_z( stiffnesses_calc_z_z( size1_x,size2_x,d_x,J1_x,J2_x ) );
       debug_disp('x-y stiffness:')
       stiffness_components(2,:) = ...
         swap_x_z( stiffnesses_calc_z_y( size1_x,size2_x,d_x,J1_x,J2_x ) );
       debug_disp('x-z stiffness:')
       stiffness_components(3,:) = ...
         swap_x_z( stiffnesses_calc_z_x( size1_x,size2_x,d_x,J1_x,J2_x ) );
       calc_xyz = swap_x_z(calc_xyz);
       calc_xyz = swap_y_z(calc_xyz);
       debug_disp('y-x stiffness:')
       stiffness_components(4,:) = ...
         swap_y_z( stiffnesses_calc_z_x( size1_y,size2_y,d_y,J1_y,J2_y ) );
       debug_disp('y-y stiffness:')
       stiffness_components(5,:) = ...
         swap_y_z( stiffnesses_calc_z_z( size1_y,size2_y,d_y,J1_y,J2_y ) );
       debug_disp('y-z stiffness:')
       stiffness_components(6,:) = ...
```

```
swap_y_z( stiffnesses_calc_z_y( size1_y,size2_y,d_y,J1_y,J2_y ) );
calc_xyz = swap_y_z(calc_xyz);
```

Functions for calculating forces and stiffnesses. The calculations for forces between differently-oriented cuboid magnets are all directly from the literature. The stiffnesses have been derived by differentiating the force expressions, but that's the easy part.

```
\(\begin{align*} Functions for calculating forces and stiffnesses \(^{15}\) \(\equiv \) Parallel magnets force calculation \(^{16}\) \(\langle \) Orthogonal magnets force calculation \(^{17}\) \(\langle \) Parallel magnets stiffness calculation \(^{20}\) \(\langle \) Orthogonal magnets stiffness calculation \(^{21a}\) \(\langle \) Helper functions \(^{26a}\)
```

The expressions here follow directly from Akoun and Yonnet [1].

```
Inputs:
                  size1=(a,b,c)
                                             the half dimensions of the fixed magnet

         calc_out = swap_x_y(stiffnesses_xyz);
         end
```

Some shared setup code. First return early if either of the magnetisations are zero — that's the trivial solution. Assume that the magnetisation has already been rounded down to zero if necessary; i.e., that we don't need to check for J1 or J2 are less than 1e-12 or whatever.

Here are some variables used above that only need to be computed once. The idea here is to vectorise instead of using for loops because it allows more convenient manipulation of the data later on.

```
22b  \( Initialise main variables 8 \) += (7) < 8

magconst = 1/(4*pi*(4*pi*1e-7));

[index_i, index_j, index_k, index_l, index_p, index_q] = ndgrid([0 1]);

index_sum = (-1).^(index_i+index_j+index_k+index_l+index_p+index_q);</pre>
```

And some shared finishing code.

```
23
      \langle Finish up 23 \rangle \equiv
                                                                         (16 17 20 21a)
         if calc_xyz(1)
           component_x = index_sum.*component_x;
         else
           component_x = 0;
         end
         if calc_xyz(2)
           component_y = index_sum.*component_y;
         else
           component_y = 0;
         \quad \text{end} \quad
         if calc_xyz(3)
           component_z = index_sum.*component_z;
           component_z = 0;
         end
         calc_out = J1*J2*magconst .* ...
           [ sum(component_x(:));
             sum(component_y(:));
             sum(component_z(:)) ] ;
         debug_disp(calc_out')
         \quad \text{end} \quad
```

Setup code.

end

Magnetisation directions are specified in either cartesian or spherical coordinates. Since this is shared code, it's sent to the end to belong in a nested function.

We don't use Matlab's sph2cart here, because it doesn't calculate zero accurately (because it uses radians and cos(pi/2) can only be evaluated to machine precision of pi rather than symbolically).

 $\langle Function for resolving magnetisations 24 \rangle \equiv$ 24 **(7)** function J = resolve_magnetisations(magn,magdir) if length(magdir)==2 $J_r = magn;$ $J_t = magdir(1);$ $J_p = magdir(2);$ $J = [J_r * cosd(J_p) * cosd(J_t) ; ...$ $J_r * cosd(J_p) * sind(J_t)$; ... $J_r * sind(J_p)$]; else if all(magdir == zeros(size(magdir))) J = [0; 0; 0];else J = magn*magdir/norm(magdir); J = reshape(J,[3 1]);endend

Forces due to magnetisations in x and y are calculated by rotating the original expressions. The rotated magnet sizes and magnetisation vectors are calculated here once only.

The rotation matrices are precalculated to avoid performing the matrix multiplications each time.

```
25a
       \langle Precompute rotations 25a \rangle \equiv
                                                                        (7)
        swap_x_y = 0(vec) vec([2 1 3]);
        swap_x_z = 0(vec) vec([3 2 1]);
        swap_y_z = 0(vec) vec([1 3 2]);
        rotate_z_to_x = @(vec) [ vec(3); vec(2); -vec(1) ]; % Ry( 90)
        rotate_x_to_z = @(vec) [ -vec(3); vec(2); vec(1) ]; % Ry(-90)
        rotate_y_to_z = @(vec) [ vec(1); -vec(3); vec(2) ]; % Rx(90)
        rotate_z_{to_y} = @(vec) [ vec(1); vec(3); -vec(2) ]; % Rx(-90)
        rotate_x_to_y = @(vec) [ -vec(2); vec(1); vec(3) ]; % Rz(90)
        rotate_y_to_x = @(vec) [ vec(2); -vec(1); vec(3)]; % Rz(-90)
        size1_x = swap_x_z(size1);
        size2_x = swap_x_z(size2);
        J1_x
                = rotate_x_to_z(J1);
         J2_x
                 = rotate_x_to_z(J2);
        size1_y = swap_y_z(size1);
        size2_y = swap_y_z(size2);
        J1_y
                 = rotate_y_to_z(J1);
        J2_y
                 = rotate_y_to_z(J2);
      And the rotated displacement vectors are calculated once per loop:
```

```
25b ⟨ Precompute displacement rotations 25b⟩≡

d_x = rotate_x_to_z(displ);

d_y = rotate_y_to_z(displ);
```

The equations contain two singularities. Specifically, the equations contain terms of the form $x \log(y)$, which becomes NaN when both x and y are zero since $\log(0)$ is negative infinity.

This function computes $x \log(y)$, special-casing the singularity to output zero, instead. (This is indeed the value of the limit.)

```
26a ⟨ Helper functions 26a⟩≡

function out = multiply_x_log_y(x,y)

out = x.*log(y);

out(~isfinite(out))=0;
end

(15) 26b>
```

Also, we're using atan instead of atan2 (otherwise the wrong results are calculated — I guess I don't totally understand that), which becomes a problem when trying to compute atan(0/0) since 0/0 is NaN.

This function computes atan but takes two arguments.

```
26b \langle Helper functions \ 26a \rangle + \equiv (15) \triangleleft 26a function out = atan1(x,y) out = zeros(size(x)); ind = x~=0 & y~=0; out(ind) = atan(x(ind)./y(ind)); end
```

Let's print some information to the terminal to aid debugging. This is especially important (for me) when looking at the rotated coordinate systems.

```
debug_disp(' ')
debug_disp('CALCULATING THINGS')
debug_disp('===========')
debug_disp('Displacement:')
debug_disp(displ')
debug_disp('Magnetisations:')
debug_disp(J1')
debug_disp(J2')
```

When users type help magnetforces this is what they see.

Test files. The chunks that follow are designed to be saved into individual files and executed automatically to check for (a) correctness and (b) regression problems as the code evolves.

How do I know if the code produces the correct forces? Well, for many cases I can compare with published values in the literature. Beyond that, I'll be setting up some tests that I can logically infer should produce the same results (such as mirror-image displacements) and test that.

There are many Matlab unit test frameworks but I'll be using a fairly low-tech method. In time this test suite should be (somehow) useable for all implementations of magnetocode, not just Matlab. But I haven't thought about doing anything like that, yet.

Because I'm lazy, just run the tests manually for now. This script must be run twice if it updates itself.

```
27b ⟨ testall.m 27b⟩≡

clc;

test001a
 test001b
 test001c
 test001d
```

Force testing. This test checks that square magnets produce the same forces in the each direction when displaced in positive and negative x, y, and z directions, respectively. In other words, this tests the function forces_calc_z_y directly. Both positive and negative magnetisations are used.

```
\langle test001a.m \ 28 \rangle \equiv
28
         disp('======;')

       disp('======;')
```

Forces between (multipole) magnet arrays. This function uses magnetforces.m to compute the forces between two multipole magnet arrays. As before, we can calculate either force and/or stiffness in all three directions.

The structure of the function itself should look fairly straightforward. Some of the code is repeated from magnetforces (an advantage of the literate programming approach) for parsing the inputs for which calculations to perform and return.

```
\langle multipole forces.m 40a \rangle \equiv
40a
           function [varargout] = multipoleforces(fixed_array, float_array, displ, varargin)
           ⟨ Matlab help text (multipole) 61a⟩
           ⟨ Parse calculation args 10⟩
           ⟨ Organise input displacements 9⟩
           ⟨ Initialise multipole variables 43⟩
             Calculate array forces 42
           ⟨ Return all results 11a⟩
           \langle Multipole sub-functions 40b \rangle
           end
        And nested sub-functions.
         \langle Multipole sub-functions 40b \rangle \equiv
40b
                                                                                         (40a)
           ⟨ Create arrays from input variables 45⟩
           ⟨ Extrapolate variables from input 60⟩
```

Table 1: Description of multipoleforces data structures.

Inputs:	fixed_array float_array displ [what to calculate]	structure describing first magnet array structure describing the second magnet array displacement between first magnet of each array 'force' and/or 'stiffness'
Outputs:	forces stiffnesses	forces on the second array stiffnesses on the second array
Arrays:	type align face mcount msize mgap magn magdir_fn	See Table 2 See Table 3 See Table 4 [i j k] magnets in each direction size of each magnet gap between successive magnets magnetisation magnitude function to calculate the magnetisation direction

Table 2: Possibilities for the type of a multipole array.

generic	Magnetisation directions &c. are defined manually
linear	Linear Halbach array
planar	Planar Halbach array
quasi-Halbach	Quasi-Halbach planar array
patchwork	'Patchwork' planar array

Table 3: Axes or plane with which to align the array, set with align.

x, y, z	For linear arrays
xy, yz, xz	For planar arrays

Table 4: Facing direction for the strong side of the array, set with face.

+x, -x	Horizontal
+y, -y	Horizontal
+z, -z, up, down	Vertical

Although the input to these functions is described in the user guide, there's a quick summary in Tables 1 and 2.

Actual calculation of the forces. To calculate these forces, let's assume that we have two large arrays enumerating the positions and magnetisations of each individual magnet in each magnet array.

Required fields for each magnet array:

total M total number of magnets in the array

 $\dim (M \times 3)$ size of each magnet

else

magloc $(M \times 3)$ location of each magnet from the local coordinate system of the array

magn $(M \times 1)$ magnetisation magnitude of each magnet

magdir $(M \times 2)$ magnetisation direction of each magnet in spherical coordinates size $(M \times 3)$ total actual dimensions of the array

Then it's just a matter of actually calculating each force and summing them together, as shown below. We'll discuss how to actually populate these data structures later.

```
\langle Calculate \ array \ forces \ 42 \rangle \equiv
42
                                                                        (40a)
       for ii = 1:fixed_array.total

        end
      This is where it begins. This is basically just initialisation, but note the impor-
      tant complete_array_from_input function. This is what takes the high-level
      Halbach array (or whatever array) descriptions and translates them into a more
      direct (if tedious) form.
      \langle Initialise multipole variables 43 \rangle \equiv
43
                                                                          (40a)
        part = @(x,y) x(y);
        fixed_array = complete_array_from_input(fixed_array);
        float_array = complete_array_from_input(float_array);
        if calc_force_bool
          array_forces = repmat(NaN,[3 Ndispl fixed_array.total float_array.total]);
        end
        if calc_stiffness_bool
          array_stiffnesses = repmat(NaN,[3 Ndispl fixed_array.total float_array.total]);
        end
        displ_from_array_corners = displ ...
          + repmat(fixed_array.size/2,[1 Ndispl]) ...
          - repmat(float_array.size/2,[1 Ndispl]);
```

From user input to array generation. We separate the force calculation from transforming the inputs into an intermediate form used for that purpose. This will hopefully allow us a little more flexibility.

This is the magic abstraction behind complete_array_from_input that allows us to write readable input code describing multipole arrays in as little detail as possible.

As input variables for a linear multipole array, we want to use some combination of the following:

- w wavelength of magnetisation
- l length of the array without magnet gaps
- N number of wavelengths
- d magnet length
- T total number of magnets
- M number of magnets per wavelength
- ϕ rotation between successive magnets

These are related via the following equations of constraint:

$$w = Md$$
 $l = Td$ $N = T/M$ $M = 360^{\circ}/\phi$ (1)

Taking logarithms and writing in matrix form yields

$$\begin{bmatrix} 1 & 0 & 0 & -1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 \end{bmatrix} \log \begin{bmatrix} w \\ l \\ N \\ d \\ T \\ M \\ \phi \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \log(360^{\circ}) \end{bmatrix}$$
 (2)

We can use this matrix to compute whichever variables we need given enough inputs.

However, we generally do not want an integer number of wavelengths of magnetisation in the magnet arrays; if T = MN then we get small lateral forces that are undesirable for stability. We prefer instead to have T = MN + 1, but this cannot be represented by our linear (after taking logarithms) algebra above. Therefore, if the user requests a total number of wavelengths of magnetisation, we automatically add one end magnet to restore the symmetry of the forces.

More variables that can be set are:

- ϕ_0 magnetisation direction of the first magnet
- q additional gap between adjacent magnet faces (optional)
- e array height (or magnet height)
- f array width (or magnet width)

For both technical reasons and reasons of convenience, the length of the array l does not take into account any specified magnet gap g. In other words, l is

actually the length of the possibly discontiguous magnetic material; the length of the array will be l + (N-1)g.

```
\langle Create \ arrays \ from \ input \ variables \ 45 \rangle \equiv
45
                                                                                    (40b)
         function array = complete_array_from_input(array)
         if ~isfield(array,'type')
           array.type = 'generic';
         ⟨ Set alignment/facing directions 48⟩
