Calculating forces between magnets	2	1
Functions for calculating forces and stiffnesses	11	6
Setup code	17	11
Test files	22	13

1. About this file. This is a 'literate programming' approach to writing Matlab code using Matlaburgham. To be honest I don't know if it's any better than simply using the Matlab programming language directly. The big advantage for me is that you have access to the entire IATEX document environment, which gives you access to vastly better tools for cross-referencing, maths typesetting, structured formatting, bibliography generation, and so on.

The downside is obviously that you miss out on Matlab's IDE with its integrated M-Lint program, debugger, profiler, and so on. Depending on ones work habits, this may be more or less of limiting factor to using 'literate programming' in this way.

2. Calculating forces between magnets. This is the source to some code to calculate the forces (and perhaps torques) between two cuboid-shaped magnets with arbitary displacement and magnetisation direction.

If this code works then I'll look at calculating the forces for magnets with rotation as well.

3. The main function is called magnetforces, which takes three arguments: magnet\_fixed, magnet\_float, and displ. These will be described below.

```
⟨magnetforces.m 3⟩ ≡
function [forces_out] =magnetforces(magnet_fixed, magnet_float, displ)
  ⟨Matlab help text 21⟩
  ⟨Extract input variables 4⟩
  ⟨Precompute rotation matrices 18⟩
  ⟨Decompose orthogonal superpositions 5⟩
  ⟨Calculate all forces 6⟩
  ⟨Functions for calculating forces and stiffnesses 11⟩
  end
```

<sup>1</sup>http://tug.ctan.org/pkg/matlabweb

4. First of all, address the data structures required for the input and output. Because displacement of a single magnet has three components, plus sizes of the faces another three, plus magnetisation strength and direction (two) makes nine in total, we use one of Matlab's structures to pass the information into the function. Otherwise we'd have an overwhelming number of input arguments.

We use spherical coordinates to represent magnetisation angle, where **phi** is the angle from the horizontal plane  $(-\pi/2 \le \phi \le \pi/2)$  and  $\theta$  is the angle around the horizontal plane  $(0 \le \theta \le 2\pi)$ . This follows Matlab's definition; other conventions are commonly used as well. Remember:

```
(1,0,0)_{\text{cartesian}} \equiv (0,0,1)_{\text{spherical}}
      (0,1,0)_{\text{cartesian}} \equiv (\pi/2,0,1)_{\text{spherical}}
      (0,0,1)_{\text{cartesian}} \equiv (0,\pi/2,1)_{\text{spherical}}
\langle \text{Extract input variables } 4 \rangle \equiv
  a_1 = 0.5*magnet\_fixed.dim(1);
  b_1 = 0.5*magnet\_fixed.dim(2);
  c_1 = 0.5*magnet\_fixed.dim(3);
  size1 = [a_1; b_1; c_1];
  a_2 = 0.5*magnet\_float.dim(1);
  b_2 = 0.5*magnet\_float.dim(2);
  c_2 = 0.5*magnet\_float.dim(3);
  size2 = [a_2; b_2; c_2];
  J1r = magnet\_fixed.magn;
  J2r = magnet\_float.magn;
  J1t = magnet\_fixed.magdir(1);
  J2t = magnet\_float.magdir(1);
  J1p = magnet\_fixed.magdir(2);
  J2p = magnet\_float.magdir(2);
  if (J1r < 0 \text{ OR } J2r < 0)
  error(['By_{\sqcup}convention,_{\sqcup}magnetisation_{\sqcup}must_{\sqcup}be_{\sqcup}positive;_{\sqcup}',\dots
        'change_the_angle_to_reverse_direction.'])
  end
```

**5.** Superposition is used to turn an arbitrary magnetisation angle into a set of orthogonal magnetisations.

Each magnet can potentially have three components, which can result in up to nine force calculations for a single magnet.

We don't use Matlab's sph2cart here, because it doesn't calculate zero accurately (because it uses radians and  $\cos(\pi/2)$  can only be evaluated to machine precision rather than symbolically).

```
 \begin{split} &\langle \, \text{Decompose orthogonal superpositions} \quad 5 \, \rangle \equiv \\ & \quad \text{displ} = \text{reshape}(\text{displ}, [3\ 1]); \qquad \text{% column vector} \\ & \quad J1 = [J1r*\cos d(J1p)*\cos d(J1t); \quad \dots \\ & \quad J1r*\cos d(J1p)*\sin d(J1t); \quad \dots \\ & \quad J1r*\sin d(J1p)]; \\ & \quad J2 = [J2r*\cos d(J2p)*\cos d(J2t); \quad \dots \\ & \quad J2r*\cos d(J2p)*\sin d(J2t); \quad \dots \\ & \quad J2r*\sin d(J2p)]; \end{split}  This code is used in section 3.
```

**6.** The expressions we have to calculate the forces assume a fixed magnet with positive z magnetisation only. Secondly, magnetisation direction of the floating magnet may only be in the positive z- or y-directions.

The parallel forces are more easily visualised; if J1z is negative, then transform the coordinate system so that up is down and down is up. Then proceed as usual and reverse the vertical forces in the last step.

The orthogonal forces require reflection and/or rotation to get the displacements in a form suitable for calculation.

Initialise a  $3 \times 3 \times 3$  array to store each force component in each direction, and fill it up by calculating

```
\langle Calculate all forces 6 \rangle \equiv
force\_components = repmat(NaN, [9 3]);
\langle Print diagnostics 7 \rangle
\langle Calculate forces x = 9 \rangle
\langle Calculate forces y = 10 \rangle
\langle Calculate forces z = 8 \rangle
forces\_out = sum(force\_components);
```

7. Let's print information to the terminal to aid debugging. This is especially important (for me) when looking at the rotated coordinate systems.

```
 \begin{split} &\langle \operatorname{Print\ diagnostics} \quad \mathbf{7} \rangle \equiv \\ &\operatorname{disp}(`_{\square\square}`) \\ &\operatorname{disp}(`\operatorname{CALCULATING}_{\square}\operatorname{FORCES}`) \\ &\operatorname{disp}(`\operatorname{Poisplacement}:') \\ &\operatorname{disp}('\operatorname{Displacement}:') \\ &\operatorname{disp}(\mathit{displ'}) \\ &\operatorname{disp}(`\operatorname{Magnetisations}:') \\ &\operatorname{disp}(J1') \\ &\operatorname{disp}(J2') \end{split}
```

This code is used in section 6.

**8.** The easy one first, where our magnetisation components align with the direction expected by the force functions.

```
 \begin{split} &\langle \text{Calculate forces } z \quad 8 \rangle \equiv \\ & \text{disp('Forces} \sqsubseteq z - z : ') \\ & \text{forces} \_ z = \text{forces} \_ \text{calc} \_ z \_ z (\text{size1}, \text{size2}, \text{displ}, \text{J1}, \text{J2}); \\ & \text{force} \_ \text{components}(7,:) = \text{forces} \_ z \_ z; \\ & \text{disp('Forces} \sqsubseteq z - y : ') \\ & \text{forces} \_ z \_ y = \text{forces} \_ \text{calc} \_ z \_ y (\text{size1}, \text{size2}, \text{displ}, \text{J1}, \text{J2}); \\ & \text{force} \_ \text{components}(8,:) = \text{forces} \_ z \_ y; \\ & \text{disp('Forces} \sqsubseteq z - x : ') \\ & \text{forces} \_ z \_ x = \text{forces} \_ \text{calc} \_ z \_ x (\text{size1}, \text{size2}, \text{displ}, \text{J1}, \text{J2}); \\ & \text{force} \_ \text{components}(9,:) = \text{forces} \_ z \_ x; \end{aligned}
```

The other forces (i.e., x and y components) require a rotation to get the magnetisations correctly aligned. In the case of the magnet sizes, the lengths are just flipped rather than rotated (in rotation, sign is important). After the forces are calculated, rotate them back to the original coordinate system.

```
\langle \text{ Calculate forces } x \mid \mathbf{9} \rangle \equiv
  size1\_rot = swap\_x\_z(size1);
  size2\_rot = swap\_x\_z(size2);
  d_rot = rotate_x_to_z(displ);
  J1\_rot = rotate\_x\_to\_z(J1);
  J2\_rot = rotate\_x\_to\_z(J2);
  disp('Forces_x-x:')
  forces_x_x = forces_calc_z_z(size1_rot, size2_rot, d_rot, J1_rot, J2_rot);
  force\_components(1, :) = rotate\_z\_to\_x(forces\_x\_x);
  disp('Forces_x-y:')
  forces\_x\_y = forces\_calc\_z\_y(size1\_rot, size2\_rot, d\_rot, J1\_rot, J2\_rot);
  force\_components(2, :) = rotate\_z\_to\_x(forces\_x\_y);
  disp('Forces<sub>□</sub>x-z:')
  forces\_x\_z = forces\_calc\_z\_y(size1\_rot, size2\_rot, d\_rot, J1\_rot, J2\_rot);
  force\_components(3, :) = rotate\_z\_to\_x(forces\_x\_z);
This code is used in section 6.
       Same again, this time making y the 'up' direction.
\langle \text{ Calculate forces } y \mid 10 \rangle \equiv
  size1\_rot = swap\_y\_z(size1);
```

```
size2\_rot = swap\_y\_z(size2);
d_rot = rotate_y_to_z(displ);
J1\_rot = rotate\_y\_to\_z(J1);
J2\_rot = rotate\_y\_to\_z(J2);
disp('Forces_y-x:')
forces_y_x = forces_calc_z_x(size1_rot, size2_rot, d_rot, J1_rot, J2_rot);
force\_components(4, :) = rotate\_z\_to\_y(forces\_y\_x);
disp('Forces_y-y:')
forces_y_y = forces_calc_z_z(size1_rot, size2_rot, d_rot, J1_rot, J2_rot);
force\_components(5, :) = rotate\_z\_to\_y(forces\_y\_y);
disp('Forces_y-z:')
forces_y_z = forces_calc_z_y(size1_rot, size2_rot, d_rot, J1_rot, J2_rot);
force\_components(6, :) = rotate\_z\_to\_y(forces\_y\_z);
```

11. Functions for calculating forces and stiffnesses. The calculations for forces between differently-oriented cuboid magnets are all directly from the literature. The stiffnesses have been derived by differentiating the force expressions, but that's the easy part.

```
\begin{split} &\langle \text{Functions for calculating forces and stiffnesses} \quad 11 \rangle \equiv \\ &\langle \text{Parallel magnets force calculation} \quad 12 \rangle \\ &\langle \text{Orthogonal magnets force calculation} \quad 13 \rangle \\ &\langle \text{Helper functions} \quad 19 \rangle \end{split} This code is used in section 3.
```

12. The expressions here follow directly from Akoun and Yonnet [1].

```
Inputs:
              size1=(a, b, c)
                                            the half dimensions of the fixed magnet
              size2=(A, B, C)
                                            the half dimensions of the floating magnet
              displ=(dx, dy, dz)
                                            distance between magnet centres
              (J, J2)
                                            magnetisations of the magnet in the z-direction
 Outputs:
             forces_xyz=(Fx, Fy, Fz)
                                            Forces of the second magnet
\langle Parallel magnets force calculation |12\rangle \equiv
  function forces_xyz = forces_calc_z_z(size1, size2, offset, J1, J2)
          % You probably want to call
            % warning off MATLAB:divideByZero
            % warning off MATLAB:log:logOfZero
       J1 = J1(3);
       J2 = J2(3);
       if (J1 \equiv 0 \text{ or } J2 \equiv 0)
       disp('Zero∟magnetisation.')
       forces\_xyz = [0; 0; 0];
       return;
       end
       \langle Forces initialise variables \frac{16}{\rangle}
       f_{-}x = \dots
       +0.5*(v.^2 - w.^2).*\log(r - u)...
       +u \cdot *v \cdot * \log(r-v) \dots
       +v * w * atan2(u * v, r * w) ...
       +0.5*r.*u;
       f_{-1}y = \dots
       +0.5*(u.^2 - w.^2).*\log(r - v)...
       +u \cdot *v \cdot * \log(r-u) \dots
       +u .* w .* atan2(u .* v, r .* w) ...
       +0.5*r.*v;
       f_{-}z = \dots
       -u \cdot * w \cdot * \log(r - u) \dots
       -v \cdot *w \cdot * \log(r-v) \dots
       +u .* v .* atan2(u .* v, r .* w) ...
       -r \cdot *w;
       fx = index_sum .* f_x;
       fy = index_sum .* f_y;
       fz = index\_sum .* f_z;
       magconst = J1*J2/(4*\pi*(4*\pi*1\cdot 10^{-7}));
       forces\_xyz = magconst.*[sum(fx(:)); sum(fy(:)); sum(fz(:))];
       disp(forces_xyz')
       end
```

```
13.
       Orthogonal magnets forces given by Yonnet and Allag [2].
\langle Orthogonal magnets force calculation 13 \rangle \equiv
  function forces_xyz = forces_calc_z_y(size1, size2, offset, J1, J2)
       J1m = J1(3);
       J2m = J2(2);
       if (J1m \equiv 0 \text{ OR } J2m \equiv 0)
       disp('Zero_magnetisation.')
       forces\_xyz = [0; 0; 0];
       return;
       end
       forces_xyz = forces_calc_z_y_plusplus(size1, size2, offset, J1, J2);
       disp(forces\_xyz')
       end
See also sections 14 and 15.
This code is used in section 11.
14.
       Don't bother with rotation matrices for the z-x case; just reflect the
coordinate system by swapping the components.
\langle Orthogonal magnets force calculation |13\rangle + \equiv
  function forces_xyz = forces_calc_z_x(size1, size2, offset, J1, J2)
       forces\_xyz = forces\_calc\_z\_y(...
         swap_x_y(size1), swap_x_y(size2), swap_x_y(offset), ...
         J1, swap_x_y(J2);
       forces_xyz = swap_x_y(forces_xyz);
       end
```

**15.** This is what it all boils down to.  $\langle \text{Orthogonal magnets force calculation } 13 \rangle + \equiv$ function forces\_xyz = forces\_calc\_z\_y\_plusplus(size1, size2, offset, J1, J2) J1 = J1(3);J2 = J2(2); $\langle$  Forces initialise variables  $\frac{16}{\rangle}$  $f_{-}x = \dots$ -multiply\_x\_log\_y( $v \cdot * w, r - u$ )... +multiply\_x\_log\_y( $v \cdot * u, r + w$ )... +multiply\_x\_log\_y( $u \cdot * w, r + v$ )...  $-0.5*u.^2.*atan1(v.*w, u.*r)...$  $-0.5*v.^2.*$  atan1 (u.\*w, v.\*r)... $-0.5*w.^2.*atan1(u.*v, w.*r);$  $f_{-}y = \dots$ 0.5\*multiply\_x\_log\_y(u .^ 2-v .^ 2, r+w)... -multiply\_x\_log\_y( $u \cdot * w, r - u$ )...  $-u * v * atan1(u * w, v * r) \dots$ -0.5\*w.\*r; $f_z = \dots$ 0.5\*multiply\_x\_log\_y(u.^2 - w.^2, r + v)... -multiply\_x\_log\_y( $u \cdot * v, r - u$ )... -u .\* w .\* atan1(u .\* v, w .\* r) ...-0.5\*v.\*r; $f_x = index_sum .* f_x;$  $f_{-}y = index_{-}sum .* f_{-}y;$  $f_z = index_sum .* f_z;$ forces\_xyz =  $J1*J2/(4*\pi*(4*\pi*1\cdot 10^{-7})).*...$  $[sum(f_x(:)); sum(f_y(:)); sum(f_z(:))];$ 

end

16. Some shared setup code. First **return** early if either of the magnetisations are zero — that's the trivial solution. Assume that the magnetisation has already been 'chopped'; i.e., that we don't need to check for J1 or J2 less than  $1 \cdot 10^{-12}$  or whatever.

(I'm using the Mathematica definition of **chop** here; in Matlab it means truncate to a certain number of significant figures.)

```
\langle Forces initialise variables | 16\rangle \equiv
         dx = offset(1);
         dy = offset(2);
         dz = offset(3);
         a = size1(1);
         b = size1(2);
         c = size1(3);
         A = size2(1);
         B = size2(2);
         C = size2(3);
         [\mathit{index\_h}, \mathit{index\_j}, \mathit{index\_k}, \mathit{index\_l}, \mathit{index\_p}, \mathit{index\_q}] = \mathsf{ndgrid}([0\ 1]);
         index\_sum = (-1).^ (index\_h + index\_j + index\_k + index\_l + index\_p + index\_k + index\_l + index\_p + index\_k + index\_l + index\_p + index\_l + in
                                 index_q);
                                 % (Using this vectorised method is less efficient than using six for
                                 % loops over [0, 1]. To be addressed.)
         u=\mathrm{dx}+A{*}(-1)\mathinner{.}\widehat{\phantom{a}}\mathrm{index}\underline{\phantom{a}}\mathrm{j}-a{*}(-1)\mathinner{.}\widehat{\phantom{a}}\mathrm{index}\underline{\phantom{a}}\mathrm{h};
         v = dy + B*(-1). index_l - b*(-1). index_k;
         w = dz + C*(-1) .^ index_q - c*(-1) .^ index_p;
         r = \operatorname{sqrt}(u \cdot \hat{2} + v \cdot \hat{2} + w \cdot \hat{2});
```

This code is used in sections 12 and 15.

## 17. Setup code.

18. When the forces are rotated we use these rotation matrices to avoid having to think too hard. Use degrees in order to compute  $sin\pi/2$  exactly!

```
\langle \text{ Precompute rotation matrices } 18 \rangle \equiv
  swap_x_y = @(vec) \ vec([2\ 1\ 3]);
  swap_x_z = @(vec) \ vec([3\ 2\ 1]);
  swap_vz = @(vec) vec([1 3 2]);
  Rx = @(\theta) [1 \ 0 \ 0; \ 0 \ cosd(\theta) - sind(\theta); \ 0 \ sind(\theta) \ cosd(\theta)];
  Ry = \mathbb{Q}(\theta) [cosd(\theta) 0 sind(\theta); 0 1 0; -sind(\theta) 0 cosd(\theta)];
  Rz = @(\theta) [cosd(\theta) - sind(\theta) 0; sind(\theta) cosd(\theta) 0; 0 0 1];
  Rx_{-}180 = Rx(180);
  Rx_{-}090 = Rx(90);
  Rx_{-}270 = Rx(-90);
  Ry_{-}180 = Ry(180);
  Ry_{-}090 = Ry(90);
  Ry_{-}270 = Ry(-90);
  Rz_{-}180 = Rz(180);
  identity\_function = @(inp) inp;
  rotate\_round\_x = @(vec) Rx\_180*vec;
  rotate\_round\_y = @(vec) Ry\_180*vec;
  rotate\_round\_z = @(vec) Rz\_180*vec;
  rotate_none = identity_function;
  rotate_z_{to_x} = @(vec) Ry_090 * vec;
  rotate_x_to_z = @(vec) Ry_270*vec;
  rotate\_z\_to\_y = @(vec) Rx\_090*vec;
  rotate_y_to_z = @(vec) Rx_270*vec;
```

19. The equations contain some odd singularities. Specifically, the equations contain terms of the form  $x \log(y)$ , which becomes NaN when both x and y are zero since log(0) is negative infinity.

This function computes  $x \log(y)$ , special-casing the singularity to output zero, instead.

```
 \begin{split} \langle \, \text{Helper functions} & \  \  \, \textbf{19} \, \rangle \equiv \\ & \textbf{function out} = \textit{multiply\_x\_log\_y}(x,y) \\ & \textit{out} = x . * \log(y); \\ & \textit{out}(\texttt{isnan}(\textit{out})) = 0; \\ & \textbf{end} \end{split}
```

See also section 20.

This code is used in section 11.

**20.** Also, we're using atan instead of atan2 (otherwise the wrong results are calculated. I guess I don't totally understand that), which becomes a problem when trying to compute atan(0/0) since 0/0 is NaN.

This function computes atan but takes two arguments.

21. When users type help magnetforces this is what they see.

**22.** Test files. The chunks that follow are designed to be saved into individual files and executed automatically to check for (a) correctness and (b) regression problems as the code evolves.

How do I know if the code produces the correct forces? Well, for many cases I can compare with published values in the literature. Beyond that, I'll be setting up some tests that I can logically infer should produce the same results (such as mirror-image displacements) and test that.

There are many Matlab unit test frameworks but I'll be using a fairly low-tech method. In time this test suite should be (somehow) useable for all implementations of magnetocode, not just Matlab.

23. Because I'm lazy, just run the tests manually for now:

```
⟨testall.m 23⟩ ≡
try
    dbquit
end
! NOT / bin/mtangle magnetforces
magforce_test001a
magforce_test001b
magforce_test001c
```

**24.** This test checks that square magnets produce the same forces in the each direction when displaced in positive and negative x, y, and z directions, respectively. In other words, this tests the function  $forces\_calc\_z\_y$  directly. Both positive and negative magnetisations are used.

```
\langle magforce\_test001a.m 24 \rangle \equiv
  clc;
  magnet\_fixed.dim = [0.04 \ 0.04 \ 0.04];
  magnet_float.dim = magnet_fixed.dim;
  magnet\_fixed.magn = 1.3;
  magnet\_float.magn = 1.3;
  offset = 0.1;
  \langle \text{ Test } z - z \text{ magnetisations } 25 \rangle
  ⟨ Assert magnetisations tests 33⟩
  \langle \text{ Test } x - x \text{ magnetisations } 26 \rangle
  ⟨ Assert magnetisations tests 33⟩
  \langle \text{ Test } y - y \text{ magnetisations } 27 \rangle
  ⟨ Assert magnetisations tests 33⟩
  disp('=======')
  disp('Tests_passed')
  disp('======;')
```

```
25.
       Testing vertical forces.
\langle \text{ Test } z - z \text{ magnetisations } 25 \rangle \equiv
  f = [];
  for ii = [1, -1]
    magnet\_fixed.magdir = [0 \ ii*90];
                                                 % ±z
     for jj = [1, -1]
       magnet\_float.magdir = [0 jj*90];
       for kk = [1, -1]
          displ = kk*[0\ 0\ offset];
          f(:, end +1) = magnetforces(magnet_fixed, magnet_float,
               displ);
          end
          end
          end
          dirforces = chop(f(3, :), 8);
          otherforces = f([1\ 2],:);
This code is used in section 24.
       Testing horizontal x forces.
\langle \text{ Test } x - x \text{ magnetisations } 26 \rangle \equiv
  f = [];
  for ii = [1, -1]
    {\it magnet\_fixed.magdir} = [90 + ii * 90 \ 0];
                                                      % ±x
    for jj = [1, -1]
       magnet\_float.magdir = [90 + jj*90 0];
       for kk = [1, -1]
          displ = kk*[offset 0 0];
          f(:, end +1) = magnetforces(magnet_fixed, magnet_float,
          end
          end
          end
          dirforces = chop(f(1, :), 8);
          otherforces = f([2\ 3],:);
```

```
27.
       Testing horizontal y forces.
\langle \text{ Test } y - y \text{ magnetisations } 27 \rangle \equiv
  f = [];

### List of Refinements in magnetforces

```
⟨magforce_test001a.m 24⟩
⟨magforce_test001b.m 28⟩
⟨magforce_test001c.m 34⟩
⟨magnetforces.m 3⟩
⟨testall.m 23⟩
⟨Assert combinations tests 37⟩ Used in section 34.
⟨Assert magnetisations tests 33⟩ Used in sections 24 and 28.
⟨Calculate all forces 6⟩ Used in section 3.
```

```
\langle \text{ Calculate forces } x \mid 9 \rangle Used in section 6.
Calculate forces y \mid 10 Used in section 6.
Calculate forces z \in \mathbb{S} Used in section 6.
(Decompose orthogonal superpositions 5)
                                                 Used in section 3.
 Extract input variables 4) Used in section 3.
Forces initialise variables 16 Used in sections 12 and 15.
Functions for calculating forces and stiffnesses 11 Used in section 3.
 Helper functions 19, 20 Used in section 11.
 Matlab help text 21 \ Used in section 3.
Orthogonal magnets force calculation 13, 14, 15 Used in section 11.
⟨ Parallel magnets force calculation 12⟩ Used in section 11.
Precompute rotation matrices 18 \ Used in section 3.
Print diagnostics 7 Used in section 6.
(Test x-x magnetisations \frac{26}{}) Used in section \frac{24}{}.
Test y-y magnetisations 27 Used in section 24.
 Test z-z magnetisations 25 Used in section 24.
Test ZXX 32 Used in section 28.
\langle \text{ Test ZXZ } 30 \rangle \text{ Used in section } 28.
(Test ZYY 31) Used in section 28.
Test ZYZ 29 Used in section 28.
(Test combinations ZY 36) Used in section 34.
(Test combinations ZZ 35) Used in section 34.
```
